

1 Syntax

An *All-Or-Nothing-Transform* AONT specifies two algorithms (AONT.Transform, AONT.Inverse), and a block length AONT.bl. Then, we can associate with AONT a domain and range, AONT.Dom, AONT.Rng $\subset \{\{0, 1\}^{\text{AONT.bl}}\}^*$ (the set of strings having length that is a multiple of AONT.bl). We call the domain the “message sequences” and the range the “pseudo-message sequences”. Then, we have that AONT.Transform : AONT.Dom \rightarrow AONT.Rng, a randomized algorithm, and AONT.Inverse : AONT.Rng \rightarrow AONT.Dom, a deterministic algorithm.

2 Correctness

The correctness condition for AONT is

$$\Pr [\text{AONT.Inverse}(\text{AONT.Transform}((m_1, m_2 \dots m_s)) = (m_1, m_2, \dots m_s))] = 1$$

where the probability is taken over all possible message sequences $(m_1, m_2 \dots m_s)$ and all possible randomness of the AONT.Transform function. We also assume that (assumed but not explicitly stated in all the papers):

$$\Pr [M, N \in \text{AONT.Dom}, |M| = |N|, X \leftarrow_s \text{AONT.Transform}(M), Y \leftarrow_s \text{AONT.Transform}(N) : |X| = |Y|] = 1$$

3 Rivest (1997)

```

GAONTind(A)
  b  $\leftarrow_s$  {0, 1}
  b'  $\leftarrow_s$  ALR
  return (b = b')

LR(M, N, i)
  if |M|  $\neq$  |N| then
    | return  $\perp$ 
  end
  if b = 0 then
    | (m1, m2, ... ms')  $\leftarrow_s$  AONT.Transform(M)
  else
    | (m1, m2, ... ms')  $\leftarrow_s$  AONT.Transform(N)
  end
  if i > s' then
    | return  $\perp$ 
  end
  mi  $\leftarrow$   $\epsilon$ 
  return (m1, m2, ... ms')

```

Then we say that the indistinguishability adversary A has AONT-IND advantage:

$$\text{Adv}_{\text{AONT}}^{\text{aont-ind}}(A) = 2 \cdot \Pr [\text{G}_{\text{AONT}}^{\text{ind}}(A)] - 1$$

4 Boyko (1999)/ Canetti et. al (2000)

<pre> $\mathbf{G}_{\text{AONT},l}^{\text{leak}}(A)$ $b \leftarrow_{\\$} \{0, 1\}$ $b' \leftarrow_{\\$} A^{\text{LR}}$ return ($b = b'$) $\text{LR}(M, N, S)$ if $M \neq N$ then return \perp end if $b = 0$ then $y \leftarrow_{\\$} \text{AONT.Transform}(M)$ else $y \leftarrow_{\\$} \text{AONT.Transform}(N)$ end if $(S \neq y) \vee (\text{Hamm}(S) > (y - l))$ then return \perp end $y \leftarrow y \ \& \ S$ return y </pre>

Note that $|M|$ is the length of the string M in bits, $\&$ is a bitwise AND and $\text{Hamm}(M)$ takes the hamming weight of M

Then we say that the leakage adversary A has l -AONT-LEAK advantage:

$$\mathbf{Adv}_{\text{AONT},l}^{\text{aont-leak}}(A) = 2 \cdot \Pr \left[\mathbf{G}_{\text{AONT},l}^{\text{leak}}(A) \right] - 1$$

5 Leakage Resilience Model

$\begin{array}{l} \text{G}_{\text{AONT},m}^{\text{lr}}(A) \\ \hline b \leftarrow_{\$} \{0, 1\} \\ b' \leftarrow_{\$} A^{\text{LR}} \\ \text{return } (b = b') \\ \\ \text{LR}(M, N, C) \\ \hline \text{if } M \neq N \text{ then} \\ \quad \text{return } \perp \\ \text{end} \\ \text{if } b = 0 \text{ then} \\ \quad y \leftarrow_{\$} \text{AONT.Transform}(M) \\ \text{else} \\ \quad y \leftarrow_{\$} \text{AONT.Transform}(N) \\ \text{end} \\ \text{if } (C \notin \mathcal{C}_{ y , (y -m)}) \text{ then} \\ \quad \text{return } \perp \\ \text{end} \\ \text{return } C(y) \end{array}$
--

Note that $\mathcal{C}_{n,m}$ is the set of boolean circuits taking n inputs and m outputs, expressed in a string in some reasonable encoding. Then, for $C \in \mathcal{C}_{n,m}$, when we run $C(S)$ for some binary string S of length n , C will take as input the bits of S and return a m bit long string.

Then we say that the leakage resilience adversary A has m -AONT-LR advantage:

$$\text{Adv}_{\text{AONT},m}^{\text{aont-lr}}(A) = 2 \cdot \Pr \left[\text{G}_{\text{AONT},m}^{\text{lr}}(A) \right] - 1$$

6 Relationship between Notions

6.1 AONT.bl – AONT – LEAK \implies AONT – IND

Theorem 6.1 *For any AONT – IND adversary A , we can construct AONT.bl – AONT – LEAK adversary B , running in the same time and making the same number of queries, such that*

$$\text{Adv}_{\text{AONT}}^{\text{aont-ind}}(A) \leq \text{Adv}_{\text{AONT}, \text{AONT.bl}}^{\text{aont-leak}}(B)$$

Here is the adversary:

```

 $B^{\text{LR}}$ 
   $b \leftarrow \$ A^{\text{SIMLR}}$ 
  return  $b$ 
 $\text{SIMLR}(M, N, i)$ 
   $mask \leftarrow \epsilon$ 
   $s \leftarrow \lceil \frac{|M|}{\text{AONT.bl}} \rceil$ 
  for  $j = 1, 2, \dots s$  do
    if  $j \neq i$  then
       $mask \leftarrow mask || 1^{\text{AONT.bl}}$ 
    else
       $mask \leftarrow mask || 0^{\text{AONT.bl}}$ 
    end
  end
  return  $\text{LR}(M, N, mask)$ 

```

6.2 $l\text{-AONT} - \text{LR} \implies l\text{-AONT} - \text{LEAK}$

Theorem 6.2 *For any $l\text{-AONT} - \text{LEAK}$ adversary A , we can construct $l\text{-AONT} - \text{LR}$ adversary B , running in the same time and making the same number of queries, such that*

$$\text{Adv}_{\text{AONT},l}^{\text{aont-leak}}(A) \leq \text{Adv}_{\text{AONT},l}^{\text{aont-lr}}(B)$$

Here is the adversary:

```

 $B^{\text{LR}}$ 
   $b \leftarrow \$ A^{\text{SIMLR}}$ 
  return  $b$ 
 $\text{SIMLR}(M, N, mask)$ 
  return  $\text{LR}(M, N, C_{mask})$ 
 $C_{mask}(X)$ 
  return  $mask \& X$ 

```

6.3 $\text{AONT} - \text{IND} \not\equiv \text{AONT.bl} - \text{AONT} - \text{LEAK}$

Consider the following AONT scheme, Checksum, which is defined for all choices of Checksum.bl. It has $\text{Checksum.Dom} = \{0, 1\}^{\text{Checksum.bl}}$ and $\text{Checksum.Rng} = \{0, 1\}^{\text{Checksum.bl}^2}$:

<u>$\text{Checksum.Transform}(m)$</u>	<u>$\text{Checksum.Inverse}(m'_1, m'_2 \dots m'_{\text{Checksum.bl}})$</u>
$m'_{\text{Checksum.bl}} \leftarrow m$ for $i = 1, 2, \dots \text{Checksum.bl} - 1$ do $m'_i \leftarrow \$ \{0, 1\}^{\text{Checksum.bl}}$ $m'_{\text{Checksum.bl}} \leftarrow m'_i \oplus m'_{\text{Checksum.bl}}$ end return $(m'_1, m'_2 \dots m'_{\text{Checksum.bl}})$	$m \leftarrow m'_{\text{Checksum.bl}}$ for $i = 1, 2, \dots \text{Checksum.bl} - 1$ do $m \leftarrow m'_i \oplus m$ end return m

First, let's show that **Checksum** is **Checksum.bl – AONT – IND** secure. Since the pseudo-message blocks are such that $m = \bigoplus_{i=1}^{\text{Checksum.bl}} m'_i$, and **Checksum.bl – 1** blocks were chosen at random, independent of m , the loss of any one block will render the distribution of the remaining blocks completely independent of m . Therefore, (much like in the one-time pad), $\text{Adv}_{\text{Checksum}}^{\text{aont-ind}}(A) = 0$ for all A .

Next, we can provide a **Checksum.bl – AONT – LEAK** adversary A .

```

 $A^{\text{LR}}$ 
  mask  $\leftarrow \epsilon$  for  $i = 1, 2 \dots \text{Checksum.bl}$  do
    | mask  $\leftarrow \text{mask} || 1^{\text{Checksum.bl}} 0$ 
  end
   $(m'_1, m'_2 \dots m'_{\text{Checksum.bl}}) \leftarrow \text{LR}(0^{\text{Checksum.bl}}, 1^{\text{Checksum.bl}}, \text{mask})$ 
   $m \leftarrow \bigoplus_{i=1}^{\text{Checksum.bl}} (m'_i)$ 
   $m \leftarrow m \ \& \ 1^{\text{Checksum.bl}} 0$ 
  if  $m = 0^{\text{Checksum.bl}}$  then
    | return 0
  else
    | return 1
  end

```

Then we have that $\text{Adv}_{\text{Checksum,Checksum.bl}}^{\text{aont-leak}}(A) = 1$, since the adversary is able to retrieve any **Checksum.bl – 1** bits of the original message.

6.4 AONT.bl – AONT – LEAK $\not\equiv$ AONT.bl – AONT – LR

This is in the context of the RO model, specifically where a secure instance of OAEP is assumed.

Consider the package transform proposed by Rivest, denoted **Package**. Note that $\text{Package.Dom} = \text{Package.Rng} = \{X \in \{0, 1\}^* : |X| \text{ is a multiple of AONT.bl}\}$

<u>Package.Transform$(m_1, m_2, \dots m_s)$</u> <pre> if $\exists i. m_i \neq \text{Package.bl}$ then return \perp end $K \leftarrow_{\\$} \{0, 1\}^{\text{Package.bl}}$ $K' \leftarrow_{\\$} \{0, 1\}^{\text{Package.bl}}$ $m'_{s+1} \leftarrow K'$ for $i = 1, 2 \dots s$ do $m'_i \leftarrow m_i \oplus E(K', \langle i \rangle_{\text{Package.bl}})$ $h_i \leftarrow E(K, m'_i \oplus \langle i \rangle_{\text{Package.bl}})$ $m'_{s+1} \leftarrow m'_{s+1} \oplus h_i$ end return $(m'_1, m'_2 \dots m'_s, m'_{s+1}, K)$ </pre>	<u>Package.Inverse$(m'_1, m'_2 \dots m'_{s'})$</u> <pre> if $(\exists i. m'_i \neq \text{Package.bl}) \vee (s' \leq 2)$ then return \perp end $K \leftarrow m'_{s'}$ $K' \leftarrow m'_{s'-1}$ $s \leftarrow s' - 2$ for $(i = 1, 2, \dots s)$ do $h_i \leftarrow E(K, m'_i \oplus i)$ $K' \leftarrow K' \oplus h_i$ end for $(i = 1, 2, \dots s)$ do $m_i \leftarrow E(K', i) \oplus m'_i$ end return $(m_1, m_2 \dots m_s)$ </pre>
--	--

Then, from Boyko (1999) we know that when OAEP is used as E , we have that **Package** is

AONT.bl – AONT – IND – LEAK is as secure as OAEP. We now present a AONT.bl – AONT – IND – LR adversary A .

```

 $A^{\text{LR}}$ 
   $X || 0^{\text{AONT.bl}} \leftarrow_{\$} \text{LR}(0^{\text{AONT.bl}}, 1^{\text{AONT.bl}}, C)$ 
  if  $X = 1^{\text{AONT.bl}}$  then
    | return 1
  else
    | return 0
  end
 $C(X)$ 
   $Y \leftarrow \text{Package.Inverse}(X)$ 
  return  $(X || 0^{\text{AONT.bl}})$ 

```

Then we have that $\mathbf{Adv}_{\text{Package, Package.bl}}^{\text{aont-lr}}(A) = 1$, by the correctness condition of the AONT. One can note that the A runs in time proportional to the running time of `Package.Inverse`, which should be PT in any usable AONT.
